Gradients

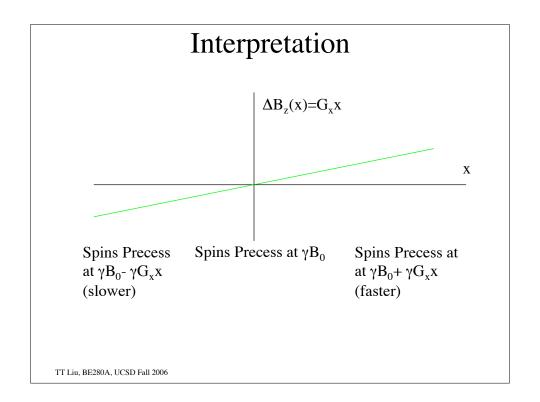

Spins precess at the Larmor frequency, which is proportional to the local magnetic field. In a constant magnetic field $B_z=B_0$, all the spins precess at the same frequency (ignoring chemical shift).

Gradient coils are used to add a spatial variation to B_z such that $B_z(x,y,z) = B_0 + \Delta B_z(x,y,z)$. Thus, spins at different physical locations will precess at different frequencies.

Gradient Fields

Gradient Fields

Define

$$\vec{G} = G_x \hat{i} + G_y \hat{j} + G_z \hat{k} \qquad \vec{r} = x \hat{i} + y \hat{j} + z \hat{k}$$

So that

$$G_x x + G_y y + G_z z = \vec{G} \cdot \vec{r}$$

Also, let the gradient fields be a function of time. Then the z-directed magnetic field at each point in the volume is given by:

$$B_z(\vec{r},t) = B_0 + \vec{G}(t) \cdot \vec{r}$$

TT Liu, BE280A, UCSD Fall 2006

Static Gradient Fields

In a uniform magnetic field, the transverse magnetization is given by:

$$M(t) = M(0)e^{-j\omega_0 t}e^{-t/T_2}$$

In the presence of non time-varying gradients we have

$$\begin{split} M(\vec{r}) &= M(\vec{r},0) e^{-j\gamma B_z(\vec{r})t} e^{-t/T_2(\vec{r})} \\ &= M(\vec{r},0) e^{-j\gamma (B_0 + \vec{G} \cdot \vec{r})t} e^{-t/T_2(\vec{r})} \\ &= M(\vec{r},0) e^{-j\omega_0 t} e^{-j\gamma \vec{G} \cdot \vec{r}t} e^{-t/T_2(\vec{r})} \end{split}$$

Time-Varying Gradient Fields

In the presence of time-varying gradients the frequency as a function of space and time is:

$$\begin{split} \omega(\vec{r},t) &= \gamma B_z(\vec{r},t) \\ &= \gamma B_0 + \gamma \vec{G}(t) \cdot \vec{r} \\ &= \omega_0 + \Delta \omega(\vec{r},t) \end{split}$$

TT Liu, BE280A, UCSD Fall 2006

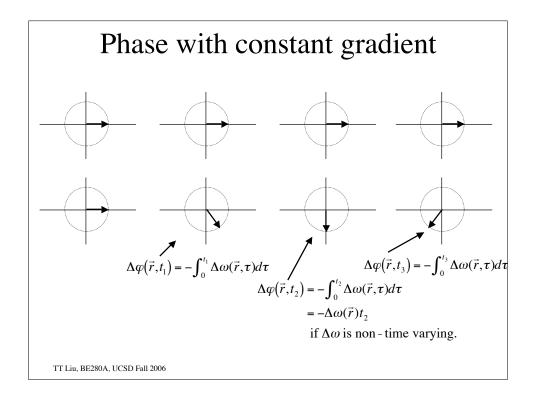

Phase

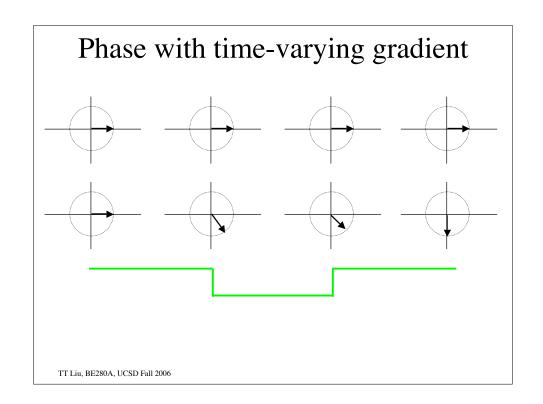

Phase = angle of the magnetization phasor Frequency = rate of change of angle (e.g. radians/sec) Phase = time integral of frequency

$$\varphi(\vec{r},t) = -\int_0^t \omega(\vec{r},\tau)d\tau$$
$$= -\omega_0 t + \Delta \varphi(\vec{r},t)$$

Where the incremental phase due to the gradients is

$$\Delta \varphi(\vec{r},t) = -\int_0^t \Delta \omega(\vec{r},\tau) d\tau$$
$$= -\int_0^t \gamma \vec{G}(\vec{r},\tau) \cdot \vec{r} d\tau$$

Time-Varying Gradient Fields

The transverse magnetization is then given by

$$\begin{split} M(\vec{r},t) &= M(\vec{r},0)e^{-t/T_2(\vec{r})}e^{\varphi(\vec{r},t)} \\ &= M(\vec{r},0)e^{-t/T_2(\vec{r})}e^{-j\omega_0 t}\exp\left(-j\int_o^t\Delta\omega(\vec{r},t)d\tau\right) \\ &= M(\vec{r},0)e^{-t/T_2(\vec{r})}e^{-j\omega_0 t}\exp\left(-j\gamma\int_o^t\vec{G}(\tau)\cdot\vec{r}d\tau\right) \end{split}$$

TT Liu, BE280A, UCSD Fall 2006

Signal Equation

Signal from a volume

$$\begin{split} s_r(t) &= \int_V M(\vec{r},t) dV \\ &= \int_x \int_y \int_z M(x,y,z,0) e^{-t/T_2(\vec{r})} e^{-j\omega_0 t} \exp\left(-j\gamma \int_o^t \vec{G}(\tau) \cdot \vec{r} d\tau\right) dx dy dz \end{split}$$

For now, consider signal from a slice along z and drop the T₂ term. Define $m(x,y) = \int_{z_0 - \Delta z/2}^{z_0 + \Delta z/2} M(\vec{r}, t) dz$

To obtain

$$s_r(t) = \int_x \int_y m(x, y) e^{-j\omega_0 t} \exp\left(-j\gamma \int_o^t \vec{G}(\tau) \cdot \vec{r} d\tau\right) dx dy$$

Signal Equation

Demodulate the signal to obtain

$$s(t) = e^{j\omega_0 t} s_r(t)$$

$$= \int_x \int_y m(x, y) \exp\left(-j\gamma \int_o^t \vec{G}(\tau) \cdot \vec{r} d\tau\right) dx dy$$

$$= \int_x \int_y m(x, y) \exp\left(-j\gamma \int_o^t \left[G_x(\tau)x + G_y(\tau)y\right] d\tau\right) dx dy$$

$$= \int_x \int_y m(x, y) \exp\left(-j2\pi \left(k_x(t)x + k_y(t)y\right)\right) dx dy$$

Where

$$k_x(t) = \frac{\gamma}{2\pi} \int_0^t G_x(\tau) d\tau$$
$$k_y(t) = \frac{\gamma}{2\pi} \int_0^t G_y(\tau) d\tau$$

TT Liu, BE280A, UCSD Fall 2006

MR signal is Fourier Transform

$$s(t) = \int_{x} \int_{y} m(x, y) \exp\left(-j2\pi \left(k_{x}(t)x + k_{y}(t)y\right)\right) dxdy$$

$$= M\left(k_{x}(t), k_{y}(t)\right)$$

$$= F\left[m(x, y)\right]_{k_{x}(t), k_{y}(t)}$$

Recap

- Frequency = rate of change of phase.
- Higher magnetic field -> higher Larmor frequency -> phase changes more rapidly with time.
- With a constant gradient G_x, spins at different x locations precess at different frequencies -> spins at greater x-values change phase more rapidly.
- With a constant gradient, distribution of phases across x locations changes with time. (phase modulation)
- More rapid change of phase with x -> higher spatial frequency k_x

TT Liu, BE280A, UCSD Fall 2006

K-space

At each point in time, the received signal is the Fourier transform of the object

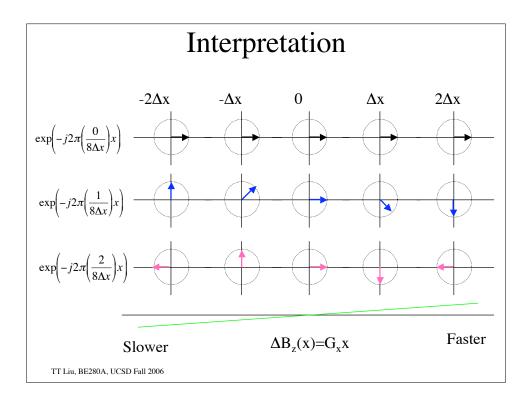

$$s(t) = M(k_x(t), k_y(t)) = F[m(x, y)]_{k_x(t), k_y(t)}$$

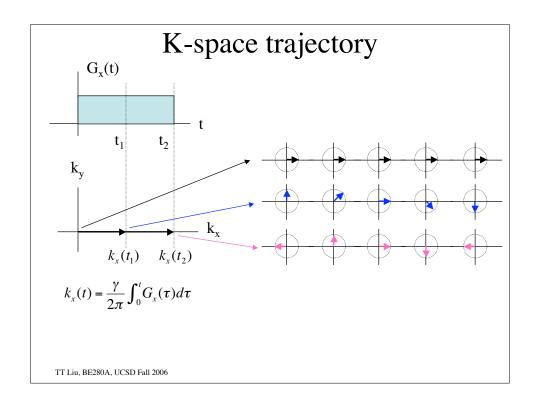

evaluated at the spatial frequencies:

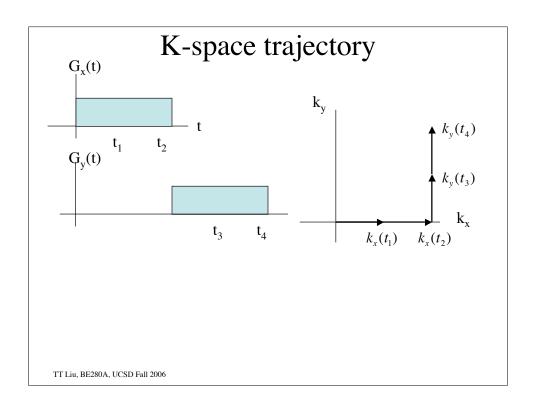

$$k_{x}(t) = \frac{\gamma}{2\pi} \int_{0}^{t} G_{x}(\tau) d\tau$$

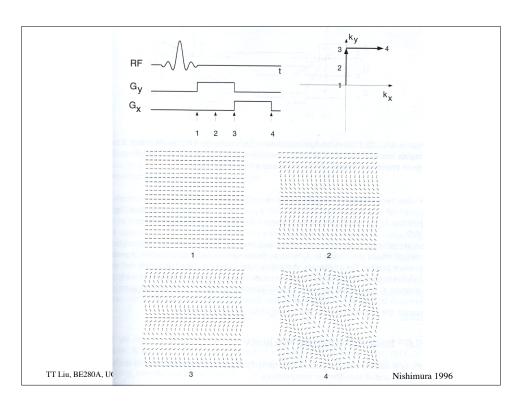

$$k_{y}(t) = \frac{\gamma}{2\pi} \int_{0}^{t} G_{y}(\tau) d\tau$$

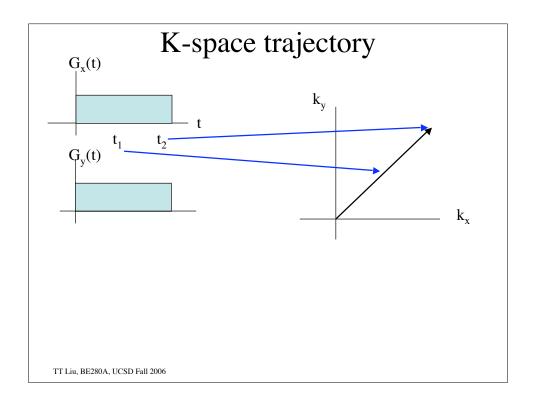

Thus, the gradients control our position in k-space. The design of an MRI pulse sequence requires us to efficiently cover enough of k-space to form our image.

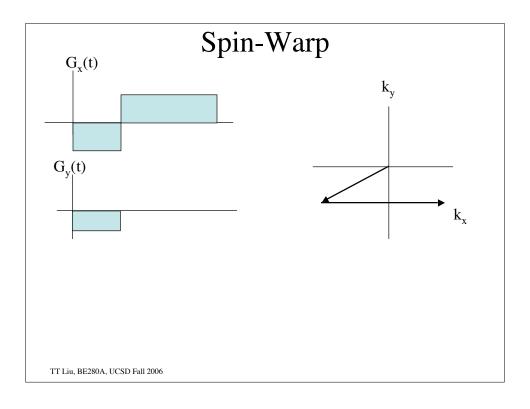

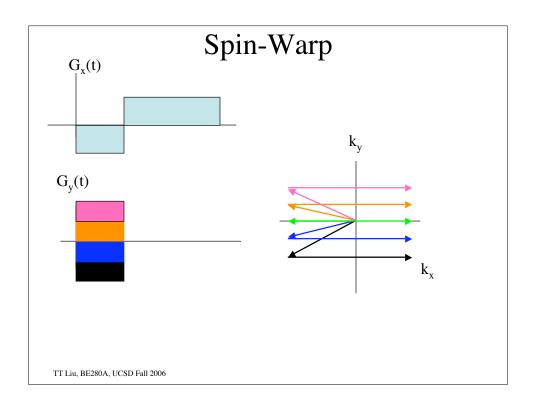

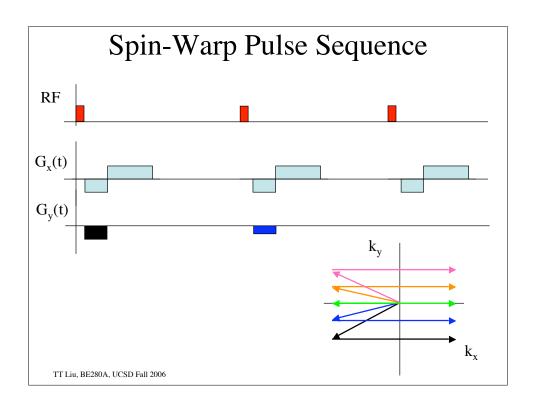

Units

Spatial frequencies (k_x, k_y) have units of 1/distance. Most commonly, 1/cm

Gradient strengths have units of (magnetic field)/distance. Most commonly G/cm or mT/m

 $\gamma/(2\pi)$ has units of Hz/G or Hz/Tesla.

$$k_{x}(t) = \frac{\gamma}{2\pi} \int_{0}^{t} G_{x}(\tau) d\tau$$

$$= [Hz/Gauss][Gauss/cm][sec]$$

$$= [1/cm]$$
