Outline

- Cerebral Blood Flow (CBF)
- Arterial Spin Labeling (ASL) Techniques
- Data Processing
- Applications of ASL

Cerebral Blood Flow (CBF)

CBF = Perfusion

= Rate of delivery of arterial blood to a capillary bed in tissue.

Units: $\frac{\text{(ml of Blood)}}{\text{(100 grams of tissue)(minute)}}$

Typical value is 60 ml/(100g-min) or
60 ml/(100 ml-min) = 0.01 s^{-1} , assuming
average density of brain equals 1 gm/ml

Fig. 2.2

High CBF

Low CBF

Time

Arterial Spin Labeling

- Magnetically tag inflowing arterial blood
- Wait for tagged blood to flow into imaging slice
- Acquire image of **tissue**+**tagged blood**
- Apply control pulse that doesn't tag blood
- Acquire control image of **tissue**
- Control image-tag image = **blood image**

Methods for Tagging Arterial Blood

- **Spatially Selective ASL (SS-ASL)** methods tag arterial blood in a region that is proximal to the imaging region of interest.
 - **Continuous ASL (CASL)** -- continuously tags blood as it passes through a thin tagging plane
 - **Pulsed ASL (PASL)** -- tags blood in a large slab proximal to imaging slice.
- **Velocity Selective ASL (VS-ASL)** tags arterial blood based on its velocity, and takes advantage of the fact that blood decelerates as it enters the capillaries and accelerates as it enters the veins.

CASL

PICORE
QUIPSS II

CASL vs. PASL

- Inherent SNR for CASL is higher, but SNR/time is roughly the same.
- Temporal resolution for PASL slightly better (2 s TR vs. 3 s TR).
- PASL amenable to use of a presaturation pulse for simultaneous CBF/BOLD.
- CASL may be better for lower slices when using a head coil for transmit.
- Both have non-quantitative variants that are useful for mapping.
- CASL has higher SAR requirements.

ASL Signal Equation

$$\Delta M = \text{CBF} \cdot A_{\text{eff}}$$

A_{eff} is the effective area of the arterial bolus. It depends on both physiology and pulse sequence parameters.

Goal: Make A_{eff} a well-controlled parameter that is robust to assumptions about physiological parameters.

Major Sources of Error for ASL

- Transit Delays
- Bolus Width in PASL
- Relaxation Effects - different relaxation rates for blood and tissue, time of exchange.
- Intravascular signal -- blood destined to perfuse more distal slices.

Transit Delays

CASL

$\sim 3 \text{ cm}$

$\Delta t < 1000 \text{ms}$

PASL

$\sim 1 \text{ cm}$

$\Delta t < 700 \text{ms}$

Controlling for Transit Delays in CASL

Voxels A and B have the same CBF, but voxel B will appear to have lower CBF if the measurement is made too early.

Arterial Bolus Width

CASL

Temporal Width of bolus determined by the pulse sequence

PASL

Temporal Width of bolus determined by arterial velocity and size of tagging slab. Underestimates global flow changes.

→ time

Velocity Selective ASL

- Velocity selective radio-frequency pulse trains were introduced by Norris and Schwarzbauer in 1999.
- Velocity Selective ASL (VS-ASL) uses a velocity selective pulse train to tag blood that is flowing faster than a desired cut-off velocity (Wong et al. 2002).
- A typical cut-off velocity is 1 cm/s which corresponds to arterioles of about 50 μm .
- Essentially **eliminates** the problem of transit delays.

Future Development of VS-ASL

- Better velocity selective pulses should improve motion insensitivity and quantitation of CBF (Abstract #2181 at this meeting)

Velocity Profile of Initial Implementation

Velocity Profile of Hyperecho based sequence with adiabatic pulses

ASL Data Processing

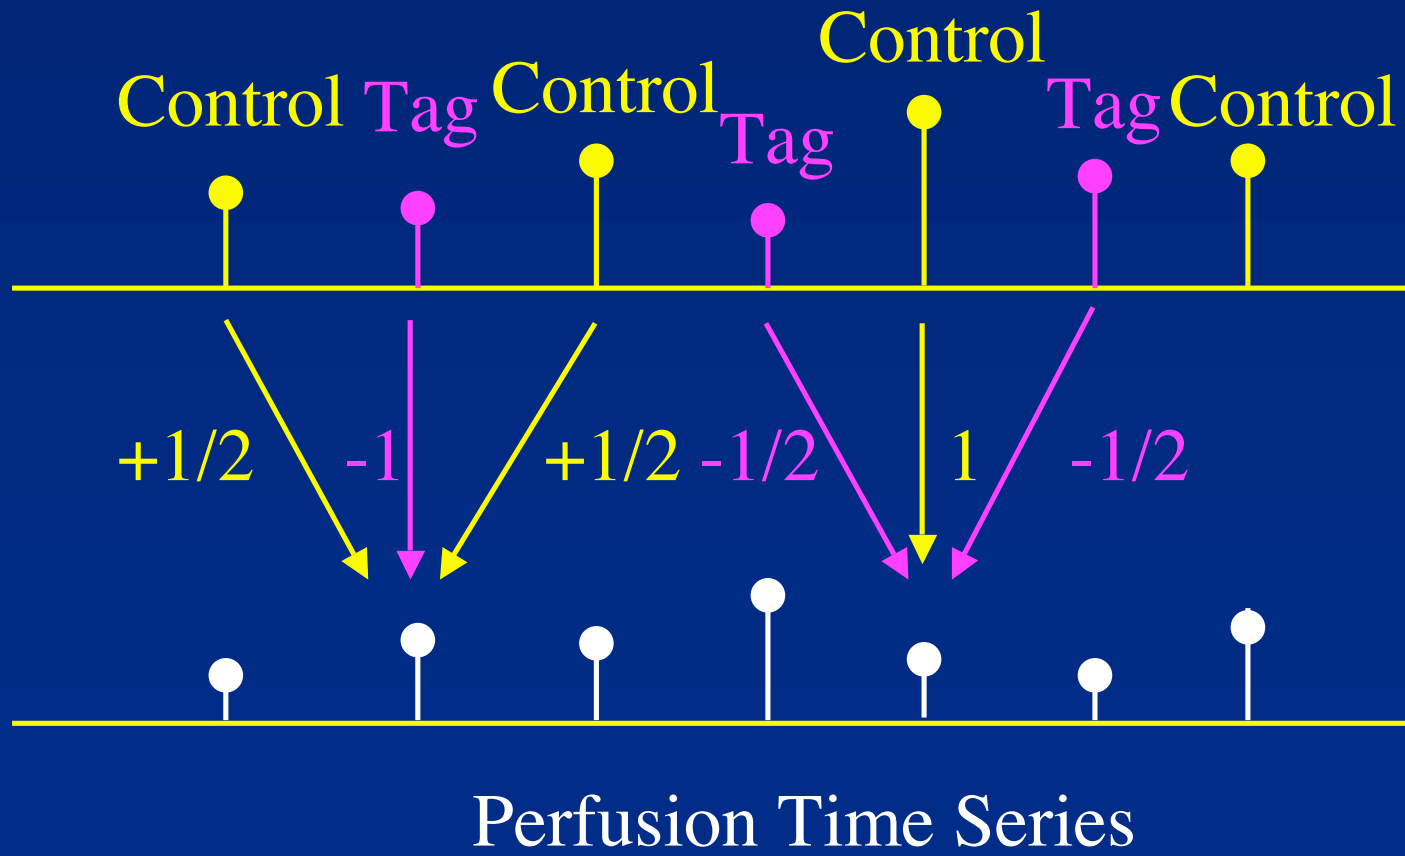

- CBF = Control - Tag
- A CBF time series is formed from a running subtraction of Control and Tag images -- pairwise subtraction, etc. .
- BOLD weighting of CBF signal is small and can be minimized with short echo time acquisitions (e.g. spiral or partial Fourier) or spin-echo acquisitions.
- Use of subtraction makes CBF signal insensitive to low-frequency drifts.

Pairwise subtraction example

Running subtraction

$T_A = 1$ to 4 seconds

ASL Data Processing

- BOLD = average of Control + Tag images
- BOLD time series is formed from the running average of Control and Tag images.
- If a presaturation pulse is used, flow weighting of BOLD signal is minimized.

ASL Measurement

Control

$T_A = 2$ to 4 s

Goal: Estimate the Hemodynamic Response

Event-related ASL

- ASL time series = **tag** time series interleaved with **control** time series
- Tag and control time series are analyzed separately.
- Tag and control time series are acquired at a reduced sampling rate, i.e. they are **downsampled**.
- Can analyze with a general linear model (GLM) with downsampling matrices to reflect the fact that tag and control are interleaved.

GLM for ASL Experiments

$$y_{\text{tag}} = D_{\text{tag}} X h_{\text{tag}} + S b_{\text{tag}} + n$$

$$y_{\text{con}} = D_{\text{con}} X h_{\text{con}} + S b_{\text{con}} + n$$

Downsampling
Matrices

Estimates \longrightarrow

$$\hat{h}_{\text{perf}} = \hat{h}_{\text{con}} - \hat{h}_{\text{tag}}$$

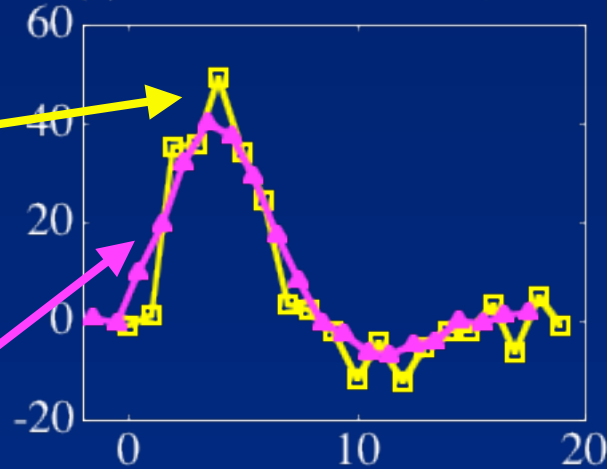

$$\hat{h}_{\text{BOLD}} = \hat{h}_{\text{con}} + \hat{h}_{\text{tag}}$$

Direct Estimate

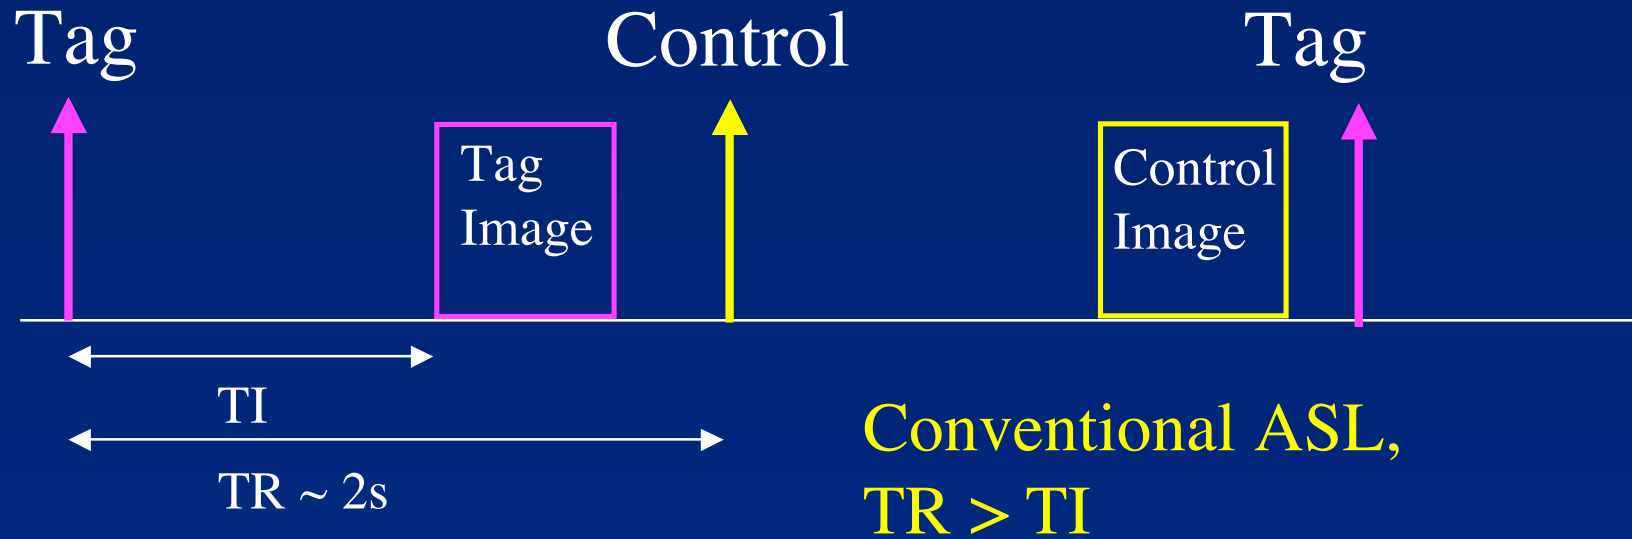

Running Subtraction Estimate

Non-quantitative ASL

- ASL signal reflects delivery of blood to capillary beds, so it is more localized than BOLD.
- Quantitative ASL has lower temporal resolution and lower CNR when compared to BOLD.
- If quantitation of CBF is not necessary, then non-quantitative ASL can be used achieve better temporal resolution and higher CNR.
- Techniques:
 - Turbo-ASL
 - Close-tag CASL

Turbo ASL

Finger Tapping

Finger Tapping

Turbo PICORE

ASL Applications

- Quantitative ASL
 - Reliable measurement of CBF across subjects, brain regions, experimental conditions, disease states, and time.
 - Simultaneous CBF/BOLD measurements to study the physiology of the fMRI response.
- Non-Quantitative ASL
 - Mapping regions of activation with better localization to the sites of neural activity.

Balloon Model

Conclusions

- ASL provides a non-invasive means of measuring CBF.
- Transit Delays must be addressed properly in order to obtain quantitative CBF with CASL and PASL.
- Velocity Selective ASL is a promising technique for dealing with long transit delays, e.g. in stroke.
- Non-quantitative ASL techniques such as Turbo-ASL and Close tag CASL have good temporal resolution and high CNR. They have the potential to provide better spatial mapping than BOLD.
